

The NCN6010 is a level shifter analog circuit designed to translate the voltages between a SIM Card and an external microcontroller. A built-in DC-DC converter makes the NCN6010 useable to drive any type of SIM card. The device fulfills the GSM 11.11 specification. The external MPU has an access to a dedicated input STOP pin, providing a way to switch off the power applied to the SIM card in case of failure or when the card is removed.

**Features**

- Supports 3.0 V or 5.0 V Operating SIM Card
- Built-in Pull Up Resistor for I/O Pin in Both Directions
- All Pins are Fully ESD Protected, According to GSM Specification
- Supports 10 MHz Clock
- 6.0 kV ESD Proof on SIM Card Pins
- These are Pb-Free Devices\*\*

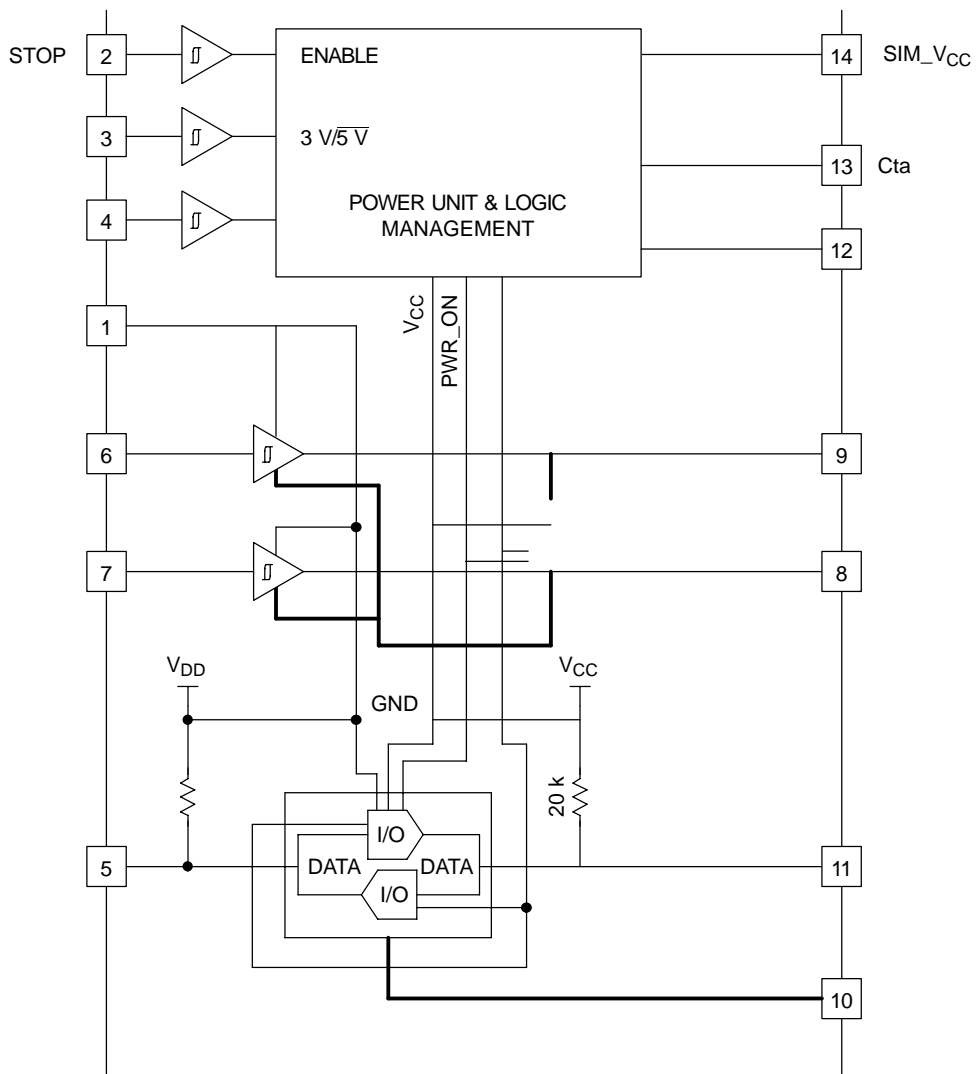

**Typical Applications**

- Cellular Phone SIM Interface
- Identification Module

Figure 3. Power On Sequence

## Power Down Operation

The power down mode can be initiated by either the PWR\_ON or by the STOP pin condition. In both cases, the communication I/O session is terminated immediately, according to the ISO7816-3 sequence as depicted in Figure 4. When the PWR\_ON signal is set Low, the NCN6010 goes to the power down mode. According to the ISO7816-3 procedure defined to deactivate the SIM contacts, the input pins I/O, CLOCK and RESET must be Low before the PWR\_ON is taken Low. When the

PWR\_ON is Low, the SIM\_IO, SIM\_CLK and SIM\_RST pins are forced to Low and the SIM\_VCC pin is left floating.

When the STOP signal is Low, the SIM\_IO, SIM\_CLK and SIM\_RST are forced Low, the SIM\_VCC being left floating, until the STOP pin is taken High again.

When the card is extracted, the external MPU shall detect the operation and run the Power Down of the card by forcing PWR\_ON input to Low. The NCN6010 fulfills the power sequence as defined by the ISO/CEI 7816-3 norm (see oscillogram given in Figure 5).

- Force SIM\_RST to Low
- Force SIM\_CLK to Low, unless it is already in this state
- Force SIM\_IO to Low
- Shut Off the SIM\_VCC supply

**Input Schmitt Triggers**

All the Logic Input pins have built-in Schmitt trigger circuits to prevent the NCN6010 against uncontrolled operation. The typical dynamic characteristics of the related pins are depicted in Figure 8.

The output signal is guaranteed to go High when the input voltage is above  $0.70 \cdot V_{bat}$ , and will go Low when the input voltage is below  $0.30 \cdot V_{bat}$ .

**Figure 10. Basic Charge Pump Operating Timings**

When the NCN6010 is programmed in the 5.0 V output voltage, the clocks are activated, switch S5 is disconnected and the output voltage is the result of the C1 charge transfer into the output load. The current is limited by three mains parameters:

- the Ron of the switching MOS (S1 through S4)
- the operating frequency
- the C1/C2 ratio and their ESR

The first parameters are depending upon the internal structure and size of the NMOS/PMOS devices used to

design the chip. The third parameter is adjustable by the user and, beside the micro farad values, the type of capacitors plays a significant role. As a matter of fact, using a low cost electrolytic model will ruin the efficiency due to the high ESR of such a capacitor. It is highly recommended to use ceramic types, preferably from the X5R or X7R series, to achieve the efficiency and the SIM\_VCC output voltage ripple. Table 2 summarizes the characteristics of the most common type of capacitors.

**Table 2. Comparison of Capacitor Types**

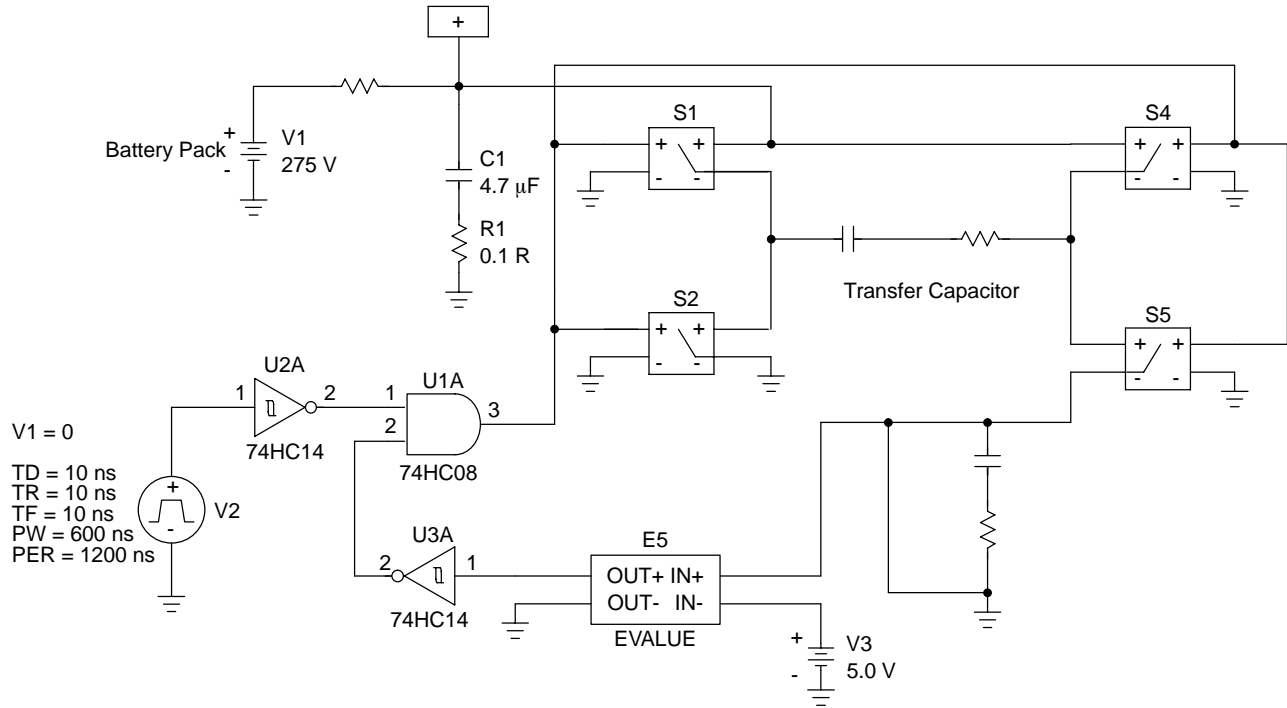

Manufacturers	Type/Serie	Format	Max Value	Tolerance	Typ. Z @ 500 kHz
---------------	------------	--------	-----------	-----------	------------------

## NCN6010

It is clear that, with nearly half an ohm of resistance in series with the pure capacitor, the tantalum or the electrolytic type will generate high voltage spikes and poor regulation in the high frequency operating charge pump built into the NCN6010. Moreover, with ESR in the 3.0 Ohm range, low cost capacitors are not suitable for this application.

Figure 11 provides the schematic diagram of the simulated charge pump circuit. Although this schematic does not

represent the accurate internal structure of the NCN6010, it can be used for engineering purpose. The ABM devices S1, S2, S4 and S5 have been defined in the PSPICE model to represent the NMOS and PMOS used in the silicon. The ESR value of C2 and C3 can be adjusted, at PSPICE level, to cope with any type of external capacitors and are useful to double check the behavior of the system as a function of the external passives components.

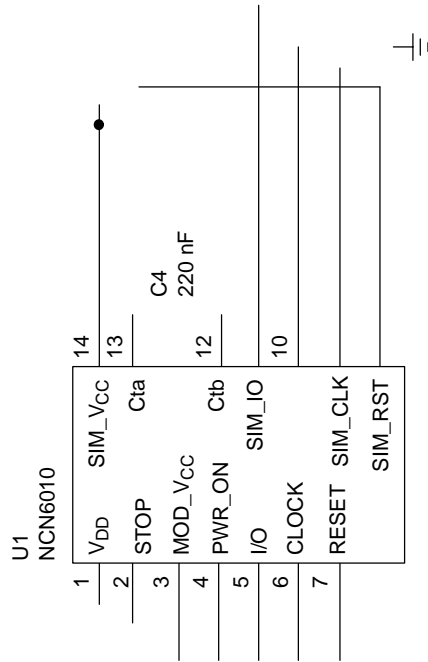

Figure 14. Engineering Test Board

## NCN6010

The layout of the PCB is a key parameter to avoid the voltage spikes that could pollute the rest of the system. Figure 16 represents a typical printed circuit lay out, based on the schematic diagram given in Figure 14, highlighting the large ground plane used in this engineering tool.

Obviously, a GSM application will use much less area, but cares must be observed to locate the capacitors as close as possible to the integrated circuit associated pins.

Capacitors C1, C2, C3, C4 and C5 are ceramic, X7R, 10 V, surface mount.
